Information and decisions needed from you

No passwords, API keys, connection strings containing credentials or browser session files should be pasted into this conversation. Provide controlled references or enter secrets directly in the selected secret store.

The current source supports continued local engineering. The entries below identify information that code inspection cannot supply. Engineering generates run IDs, hashes, configuration drafts and technical evidence; you do not need to invent them.

Item	What is needed and why	Who supplies it / where to obtain it	What can be prefilled	Work that continues while waiting
U01 Delivery scope	Confirm the next milestone, pilot organization/cohort, countries, modules and whether Phase 2B uses an isolated pilot environment. This determines which controls are applicable.	Product/platform owner. Start with what-next/system-evaluation-2026-08-28-action-plan.md and actual customer commitments.	QUALIFIED_FOR_CONTROLLED_PHASE_2B_PILOT, current EN/FR routes and documented narrow cohort are the provisional proposal.	Dependency, storage, finance and gate corrections; local tests.
U02 Register establishment	Real owner name, organization/project, verified account, authority scope and source establishing that authority; nominate a person to verify identity/authority. This establishes who may adopt the approval process.	Actual owner. Use organization mandate/appointment records, or actual project ownership records where individually owned. The verifier checks the source and an independently established contact/account binding.	Existing blueprint, setup draft, artifact hashes and proposed scopes. No earlier approval ID is needed to start setup.	Build and test register draft/storage/decision functionality without activation.
U03 People and responsibility	Assign real accounts to product budget approval, security/evidence authorization, SRE, QA, release ownership and the external-accountant test persona as applicable. Record acceptance and any required backups.	Owner and named staff, from the real identity directory and responsibility records. A seeded fixture user is a test identity, not evidence that it is the owner.	Permission/scoping matrix and current role codes. Compatible responsibilities may be combined where existing policy permits; retain required independent decisions.	Prepare role mapping, screens and negative tests using synthetic identities.
U04 X1 decisions	Actual product decision on the performance budgets and actual evidence authorization covering environment, fixture, role, data, routes and validity. These allow official capture/review.	Product approver and security/evidence owner. Review the contract manifest in docs/X1 and the existing X1 product approval form; record decisions through the recognized process once established, or a genuinely recognized external process.	Contract revision/digest, route matrix, proposed budgets and evidence scope. Engineering creates the run ID and hash bindings.	Local non-certifying fixture tests, measurement harness validation and all unrelated engineering.
U05 Test/deployment access	Approved isolated test target and later pilot/production environment identifiers, database owner, private artifact-store reference and controlled access to the existing deployment configuration. Actual restore and migration evidence is generated after access is available.	Platform/database operator. Obtain from cloud/project configuration, vault/workload identity and backup operations. Share references, not credentials.	Migration catalog, environment checklist and candidate dependency graph. Existing approvals determine which target can be changed.	Read-only source checks and mocked/pure tests. No production target is needed for ordinary source edits.

Item	What is needed and why	Who supplies it / where to obtain it	What can be prefilled	Work that continues while waiting
U06 Signing/records operations	Adopt the signing/verification method, authority validity limits, record retention/access rules and responsibility for revocation. Choose the private store and trusted reviewer-accessible origin.	Owner, records/security operator and relevant advisers where organization policy requires them. Use actual operating policy and storage configuration.	Native fresh-auth confirmation and immutable decision/event design from the September 3 blueprint.	Schema, resolver and synthetic approval tests; no issuance of real approvals.
U07 Included statutory scope	Qualified reviewer and independent checker decisions for the country rules actually included in pilot/production. Evidence must identify the reviewed source/fixture revisions and limits.	Finance/compliance owner appoints the qualified reviewer; use the existing Cameroon source bundle and real professional review.	Source hashes, fixture families, calculated differences and review packet.	Non-statutory engineering and test fixtures. Removing scope requires an explicit product/compliance decision; it is not a technical gate bypass.
U08 Operations and financial meaning	Log/alert destination, retention and responsible operator; finance owner's confirmation of recognized COGS/date/source rules for replacing the mutable-cost analytics.	SRE/security owner from monitoring configuration; finance owner from the actual accounting/valuation procedure.	Safe event schema, suggested alert exercise and old/new metric comparison.	Implementation behind a non-production switch and isolated reconciliation tests.

What you will do when the register is implemented

Open the setup draft, provide U02 and accept the exact process/appointments. Once establishment is verified and the register is activated, open My approvals, review the exact request revision, select the real decision and confirm with fresh authentication.

Stoquify should then issue the approval record ID, verified timestamp, verification/event reference and permanent record URI. Copy those generated values into the matching X1 intake fields. Reuse the URI only where the record exposes the corresponding value and verification evidence. A draft filename, generated hash or simulator ID is not an issued approval.

Signing alone does not clear X1: the decision must be valid and in scope, and the fresh authenticated technical evidence must satisfy the approved budgets and coverage requirements. This audit issued no approvals and activated no release.
