Information needed from the owner

The design and isolated prototype are complete without these answers. The following information is not recoverable from source code. It is needed at the indicated implementation/pilot stage; it is not a new list of approvals required before ordinary engineering can proceed.

Start with D01: choose the first real organization and reconciliation journey. Engineering should generate technical identifiers, impact calculations, hashes and test evidence. You should provide business choices, actual people/authority and references to recognized records—not invent system-generated IDs.

Item / when	What you provide	Who owns the answer	Where to get it	What engineering supplies / what can proceed meanwhile
D01 First customer and journey / before integration pilot	Organization name or existing tenant ID; country/legal entity; test versus pilot environment; account/payment source; expected user roles and the intended reconciliation outcome.	Product/platform owner with finance owner.	Actual customer commitment, organization settings, chart/account register and pilot plan. Current Phase 2B proposal is a starting point, not a confirmed commitment.	Source catalogue, suggested reconciliation→finance/accounting slice, synthetic fixtures and read-only preview work.
D02 Real accountable people / before governed activation	Names and verified account references for product decision, finance, security/evidence, database/SRE and release/QA as applicable; who may approve which scope.	Actual owner appoints responsible people.	Existing identity directory, appointments/mandate or project ownership evidence, with accepted responsibility. Compatible roles may be combined where policy allows; preserve required independent decisions.	Role matrix and evidence packet; source corrections and synthetic negative tests. A fixture user cannot establish real authority.
D03 Commercial offer and legacy rights / before enforced commercial migration	Which outcomes are included in each offer; which existing customers retain current access; trial/grace/expiry rules; limits and whether any change is chargeable.	Product/commercial owner.	Actual signed customer terms, approved price list and existing customer commitments. If none exist, adopt an explicit policy before enforcement.	Effective-rights comparison and configuration model. No approved prices were found or assumed. New purchase acceptance remains explicit.
D04 Country/activity scope / before payroll, statutory or fiscal pilot	Countries and activities actually included; qualified reviewer and independent checker where required; approved source/rule/fixture version references.	Finance/compliance owner.	Existing country-pack source bundles and real professional review records. UI language alone does not identify jurisdiction.	Rule/source hashes, fixture calculations, applicability matrix and setup draft; unrelated module work continues.
D05 Retention, deactivation and continuation / before commercial suspension rollout	Which historical records roles may read/export; treatment of open supplier/payroll/offline obligations; actual retention/hold and security-revocation policy.	Records/security owner with finance and relevant advisers.	Organization records policy, customer terms, actual business procedures and applicable reviewed obligations.	Obligation inventory, proposed retained-read capability and failure scenarios. Do not guess legal retention periods.

Item / when	What you provide	Who owns the answer	Where to get it	What engineering supplies / what can proceed meanwhile
D06 Environment and operating references / before integration and pilot evidence	Authorized isolated target, responsible DB/platform operator, private storage origin/reference, monitoring destination, expected volumes and support hours.	Platform/ SRE and database owners.	Existing cloud/deployment configuration, backup procedures, monitoring console and workload estimates. Provide references, not secrets.	Proposed migrations and tests, observability fields, performance harness and recovery procedure. Operators grant access through established credential/workload identity mechanisms.
D07 Approval-register establishment and X1 / before decisions are accepted as authority	Actual ownership/authority source, verified approver accounts, adopted signing/verification method, private reviewer-accessible register origin, and real scoped product/evidence decisions for X1.	Owner plus records/security and applicable approvers.	September 3 register blueprint/operating guide, actual appointment/ownership evidence and current X1 contract/form. Signing an unsigned form is not the whole establishment process.	Setup draft, exact source/version bindings, technical evidence and integration code after authorization. A working register issues record ID, verified time, signature/event reference and permanent URI; the user does not manufacture these.
D08 External providers / before provider-backed provisioning or payments	Chosen bank/payment/billing source, account/connection owner, approved use and commercial terms; whether an external ledger is a reporting destination or a proposed accounting authority.	Finance/commercial and platform owners.	Actual provider account, contract and integration settings. Enter secrets only through the configured secret store.	Adapter contract, scoped connection schema and synthetic inbox/retry tests. No provider purchase, new billing service or second ledger authority is assumed.

How this relates to the forms you already have

Use the existing approval-register start guide and Astra owner actions. This file narrows the choices for module composition; it does not replace X1's approval contract or add another signature form.

When the recognized register is operational, the authorized person reviews the exact request version and records the real decision. The register generates the issued approval ID, verified signing timestamp, verification/event reference and permanent signed-record URI. Copy those generated values into the matching X1 fields. Reuse a URI only if that record exposes the corresponding value and verification evidence. A draft path, hash or local simulator identifier is not an authenticated approval reference.

Actual X1 completion still depends on the scoped decision and technical evidence meeting the approved contract. This composition design neither lifts X1 nor blocks ordinary local design/coding while the owner supplies missing information.

Assumptions to revisit during implementation

- The next proof uses existing reconciliation with finance/accounting, preserving current required edges.
- Stoquify initially remains one deployment/database with explicit domain ownership.
- The internal financial integrity capability is included with activity that needs it; specialist workspace packaging remains a commercial decision.

- Existing client rights are reconciled and preserved during migration unless an authorized, explicit change applies.
- The first supported modules are internal application code. Executable third-party extensions and a marketplace are separate future scope.
- The illustrative five recipes, module versions and meters are design examples. They are not current subscription claims, approved prices or certified country coverage.
