Application migration and browser follow-up

Date: 24 September 2026. The user explicitly requested completion of the application posting-cycle migration and the cashier/French drawer checks. This follow-up preserves the earlier verification records as historical evidence.

Application database

The exact approved migration completed on `localhost:5432/stoquify_replay_next_20260830`. See application-migration-result.json and full-commit-readiness.md. The column, default, validated constraint, replacement unique index and matching completed Prisma migration record were verified. All 86 prior migration records and unrelated idempotency protection remained unchanged. The specific missing-column blocker is resolved.

French drawer: bounded functional verification passed

The actual in-app browser rendered `/fr/dashboard/finance/cash-drawer` for the existing accountant account. Observed checks:

- French dashboard sections, location/period controls, monetary/date formatting, drawer overview, movement, session reconciliation and journal rendered.
- Selecting one existing location restricted the initial 13 drawers to its one matching drawer; a location without sessions displayed the localized empty state.
- Keyboard Down/Down/Enter in the reporting-period menu selected `7 derniers jours`; the selected value and updated date range were observed after the data request completed.
- Related POS, reconciliation, terminal, cash-flow and history links retained their `/fr/` prefixes.
- Session details expanded with `aria-expanded=true` and a localized collapse label. Both open and closed session details were inspected without performing any financial mutation.
- The visible dashboard had no document-level horizontal overflow at the actual measured viewport: `innerWidth=927`, `innerHeight=521`, document/client width 916 CSS pixels. A screenshot was emitted in the task. Requested 1440×900, 1024×768 and 390×844 overrides did not change the measured viewport, so this is not three-breakpoint evidence. The viewport override was reset.
- Original filters were restored and observed again: `Tous les lieux` and `Aujourd'hui`. No drawer/shift records were modified by these read-only interactions.

The earlier load timeouts are historical. This follow-up establishes successful functional rendering after the page loaded; it is not a performance benchmark, assistive-technology certification, or proof of every mobile/zoom condition. Several French strings still omit accents; functional localization does not certify editorial quality.

Observed display correction

Before correction, an open session's absent closing balance displayed a numeric zero. The service preserves `closingBalance: null`, but the component passed it to a money formatter whose default is zero.

The single changed display expression in `components/pos/CashDrawerManagementDashboard.tsx` now uses the existing localized `common.notAvailable` value for null. Actual numeric balances still use the currency formatter. The browser showed `Non disponible` for the open session and the recorded numeric amount for a closed

session after the change. A genuine numeric-zero fixture was not separately exercised in the browser; the strict null branch preserves zero in source.

Evidence: pre-fix metadata, `drawer-closing-balance.before.tsx.txt`, and `drawer-closing-balance-verification.json`. Scoped ESLint exited 0 with no diagnostics. Source comparison confirmed this was the only edit to that component. The earlier full project typecheck predates this display-only change; it is not relabeled as a new full-tree run.

Cashier: awaiting authorized session

The current in-app English POS tab still showed `Point of sale access is required`. Its existing accountant session lacks POS access. Inspection of the user's existing Edge POS tab timed out before a usable state was returned. An asynchronous request asks the user to sign in using an existing cashier or manager account; no response confirming readiness had arrived when this record was written.

A smaller supported Edge DOM read also failed before the browser command could be dispatched. A final read of the in-app `/en/dashboard/pos` still showed the permission-required heading; that tab was retained for the account handoff. These are concrete access/browser blockers, not evidence of a completed cashier checkout.

No role assignment, impersonated session, password reset, live charge, sale submission, refund, void or shift close was used to obtain a pass. The cashier flow is not marked complete until an authorized session can be observed and tested. The request to open the existing POS panel was queued by the app, which is not proof the user has seen or completed the handoff.
