

Transaction History Visibility Investigation Prompt

I expected the completed transaction-history integration workflow to produce visible product changes for client/customer histories, supplier histories, cashier histories, payment/cash histories, and related operational transaction dashboards.

However, I am not seeing those changes in the application.

Please investigate what actually happened.

Use the transaction-history orchestrator evidence, run manifests, stage reports, and current codebase state to answer:

1. Which transaction-history slice was actually completed?
2. Which lanes and domains were included in that completed slice?
3. Did the workflow implement only the foundation/inventory pilot, or did it also implement client, supplier, cashier, payment, AP, and AR history surfaces?
4. Which files were actually changed for user-visible transaction-history UI?
5. Which expected domains remain unimplemented, blocked, or deferred?
6. Whether the Stage 07 PASS means "all transaction histories are complete" or only "the current foundation-inventory slice passed dev/test verification."
7. What exact next workflow should be run to implement the missing client, supplier, cashier, payment, AP, and AR histories.

Be concrete. Ground the explanation in actual files and artifacts. Do not assume completion from the word "PASS." Distinguish clearly between:

- completed foundation work,
- implemented inventory movement history,
- release/evidence verification,
- and still-pending domain history pages.

Then propose the next execution plan to make the missing transaction-history surfaces visible in the product.
