Stoquify customer retention and switching costs

Evidence based codebase assessment

12 October 2026

Stoquify has a credible foundation for strong, value-based switching costs, especially for a business using several locations, purchasing, reconciliation, and accounting together. It does not yet have demonstrated customer retention strength.

The strongest reason to stay would be **the continuity of a customer's operating records, controls, and working routines**. Leaving would mean reproducing relationships between transactions, stock, payments, approvals, and accounting evidence - not simply transferring a product catalogue.

My principal concern is that **the breadth of the implementation exceeds the evidence available for customer adoption, ease of use, and production operation**. A large platform creates retention only when customers successfully move important work into it and repeatedly get reliable results.

What this assessment covers

I inspected the current working tree at base commit **6f7f6741**. It contained 400 modified and 4,202 untracked entries at the initial check. These findings describe that checkout, including local work; they are not claims about what is deployed.

Installed versions match the npm lockfile: Next.js **15.5.18**, React **19.2.6**, Prisma **6.19.3**, Better Auth **1.6.14**, and TypeScript **5.8.3**. Prisma declares PostgreSQL. See the lockfile [1] and database configuration [2].

The graphs date from August 9. I used service nodes commitPOSSale() - community 20, postPOSStockIssue() - community 9, and exportClosePack() - community 22 to guide inspection. Two sampled action files differ from their recorded graph hashes, so the graphs are navigation evidence only. Graph refresh record [3]; service graph [4].

1 Where retention and switching costs actually come from

In this evidence register, "implemented" means present in the inspected source. Confidence concerns the source finding; commercial effects remain hypotheses without customer usage data.

POS to stock to accounting

Implementation evidence: Sale commit invokes stock issue, accounting posting, and a finalized business event. The checkout also retains requests for recovery. Sale commit [5].

Customer value and switching cost: Customers would need to reconcile stock, receipts, payment balances, and accounting at cutover, then retrain cashiers. This is substantial operational dependence.

Weakness or missing evidence: No checkout latency, failure-rate, or live reliability measurements inspected.

Confidence: High source; adoption unknown.

Purchasing and supplier payments

Implementation evidence: Goods receipt calls the inventory posting service. Payment release records reviewed execution evidence awaiting reconciliation. Receiving [6]; payment release [7].

Customer value and switching cost: Open orders, receipts, invoices, approvals, and payment evidence become a connected operating history. Replacing it requires preserving outstanding obligations and their status.

Weakness or missing evidence: Recording executed payment evidence does not establish that Stoquify actually initiates the bank or mobile-money transfer.

Confidence: High source; adoption unknown.

Reconciliation and period close

Implementation evidence: Matching handles competing claims and already allocated evidence. Close packs include findings, evidence references, reviews, and comments. Matching [8]; close pack [9].

Customer value and switching cost: This is the strongest accumulated-value mechanism: customers retain explanations for their numbers, unresolved exceptions, and review decisions.

Weakness or missing evidence: Successful real-world closes, accountant acceptance, and reductions in close effort are unverified.

Confidence: High source; adoption unknown.

Teams locations and accountants

Implementation evidence: Operating access supports location scope; accountant access has consent, expiry, revocation, and a client portfolio. Operating scope [10]; accountant portfolio [11].

Customer value and switching cost: Replacing shared permissions, responsibilities, review routines, and accountant collaboration adds organizational switching cost.

Weakness or missing evidence: No evidence of active multi-role teams or accountants managing paying clients. These features do not yet demonstrate a network effect.

Confidence: High source; adoption unknown.

Daily management routines

Implementation evidence: Daily digest composes payment, inventory, close, and operating snapshots into role-sensitive signals and actions. Digest service [12].

Customer value and switching cost: Could make Stoquify the place managers begin their day and resolve problems.

Weakness or missing evidence: A generated action queue is not evidence that managers use it or resolve more problems.

Confidence: High source; habitual use unknown.

Offline operation

Implementation evidence: Device identity, policy expiry, sequence conflicts, replay, and close-blocking evidence are represented. Offline synchronization [13].

Customer value and switching cost: Reliable disconnected selling could be highly valuable; migration would require device setup and reconciliation of pending events.

Weakness or missing evidence: Browser durability, real connectivity interruptions, and recovery performance were not tested.

Confidence: High source; operational benefit unverified.

Local accounting and payroll

Implementation evidence: Accounting setup checks SYSCOHADA mappings. The bundled country registry contains Cameroon; payroll capabilities include explicit draft/review limitations. Accounting checks [14]; country registry [15].

Customer value and switching cost: Reviewed local rules and accountant-approved configurations could be difficult and expensive to replace.

Weakness or missing evidence: The present payroll and country-pack limits materially reduce how much retention value can be credited today.

Confidence: High source; production coverage limited.

Onboarding and portability

Implementation evidence: Staged master-data imports and several domain exports exist. Imports explicitly exclude opening balances, opening stock, and historical transactions. Import boundary [16].

Customer value and switching cost: Import mappings and successful setup help adoption. Complete exports would build confidence in entrusting more work to Stoquify.

Weakness or missing evidence: Neither a complete migration-in journey nor a complete migration-out package was established.

Confidence: High for inspected boundaries; medium for overall completeness.

2 The important limits

Payroll should not currently count as a fully established retention advantage. The bundled Cameroon pack sets CNPS to SUPPORTED_DRAFT and IRPP production calculation support to false. Production admission requires supported, independently reviewed evidence and currently restricts admission to Cameroon monthly payroll. The authority worker also defaults to a sandbox adapter unless another adapter is supplied. These are meaningful implementation boundaries, not proof of broad production payroll coverage. Country pack [17]; production admission [18]; worker default [19].

Integration depth is less established than the surrounding controls. I found a generic mobile-money HMAC adapter and statement-ingestion logic. Naming a provider or accepting its reference does not prove a working native connection, live settlement feed, or supported operational relationship. I would credit the reconciliation infrastructure, but withhold credit for a mature integration ecosystem. Adapter [20].

Onboarding can constrain retention before switching costs ever develop. Importing products, customers, and suppliers is useful, but an existing business also needs trustworthy opening stock, outstanding receivables/payables, and accounting balances. The master-data importer deliberately excludes these. That is a sensible ownership boundary; it also means the customer needs a coordinated cutover journey through other domain workflows.

Usability remains an open question. Source shows recovery actions and differentiated error states, but I did not render the application. I cannot call the workflows fast, intuitive, or accessible. There are signs of terminology friction: the French close-page description mixes French with "Readiness," "ledger," and "readiness" concepts. That is a concrete copy issue, not sufficient evidence of general poor usability. Close page [21].

Retention measurement is not established. The onboarding dashboard's adoption figures cover the **recent 12 import batches**. They are not customer-retention cohorts. Searches across the inspected application areas did not establish a subscription churn, cancellation-reason, or organization-level retention reporting system. An external analytics system could exist; none was inspected. Onboarding metrics [22].

3 Portability cancellation and artificial friction

Stoquify already exports useful information, including records with identifiers, hashes, filter scope, and timestamps. However, **report exports and evidence packs are not automatically migration packages**.

• The customer summary export explicitly redacts email, phone, address, tax ID, credit limit, balance, and notes. That can be appropriate for a restricted report, but cannot serve as a complete authorized customer-directory migration. Customer export fields [23].

• AP history exports preserve source and accounting references, but expressly describe a current operational view, not a complete supplier balance or certified historical trial balance. The inspected path uses a 5,000-row bound and an 8 MiB content limit. AP export [24].

• Close packs carry evidence relationships, reviews, and comments, but include redacted summaries and source references. Their contents do not establish that every underlying attachment and operational record can be reconstructed elsewhere. Close evidence export [25].

Cancellation is less clear. Module composition explicitly reports no_purchase and preserves existing access when modules leave the selected workspace. Stopping new work is supported for some modules, while POS, sales, and reconciliation stopping remain unsupported in the inspected policy. **This is module lifecycle management, not a verified subscription cancellation journey.** Composition [26]; stop policies [27].

There is also a policy detail to resolve before designing post-cancellation access: the entitlement evaluator treats export separately from read, so a read-only entitlement can reject export when enforced. Some export paths instead request read access and apply separate export controls. You cannot assume that "read-only archive access" guarantees consistent export access. Entitlement logic [28].

My recommendation is to complete authorized portability and explicitly define archive access. **Incomplete exports should be treated as a product gap, not counted as a competitive advantage.**

4 Qualitative scorecard

These scores assess the **source-supported foundation for retention**, not measured customer retention.

Scale: **0** no evidence found; **1** fragments; **2** partial capability with major gaps; **3** connected implementation with material uncertainties; **4** substantial depth across the inspected workflow; **5** comprehensive implementation and verification for a clearly bounded scope.

Dimension	Score	Judgment
Daily operational dependence	4/5	Strong connections between sales, inventory, payments, and accounting
Accumulated history and review evidence	4/5	Rich relationships and retained decision context
Team and accountant embedding	3/5	Useful collaboration infrastructure; actual participation unknown
Daily habit and ease of adoption	2/5	Digest and onboarding foundations; activation and usability unproven
External integration depth	2/5	Ingestion and controls present; live connector breadth unestablished
Local regulatory differentiation	2/5	Concrete Cameroon/SYSCOHADA work, with material payroll limitations
Trustworthy exit and portability	2/5	Useful domain exports; complete offboarding unverified
Ability to measure retention	1/5	Operational evidence exists, but commercial cohort measurement was not established

I would not average these into a "retention percentage." A single unreliable core workflow can outweigh several sophisticated supporting modules.

5 What departure would involve

These are hypotheses assuming progressively deeper, successful adoption. Time on the platform alone does not create dependence.

Small single location retailer

After 30 days - Low to moderate: Move catalogue, establish stock and balances, retrain cashier. Often still feasible to restart elsewhere.

After 6 months - Moderate: Reconcile sales, customer credit, returns, and supplier obligations; preserve useful history.

After 12 months - Moderate to high only with broader use: Purchasing and close routines add dependence. POS-only use remains comparatively replaceable.

Growing multi location business

After 30 days - Moderate: Reproduce locations, permissions, terminals, stock configuration, and opening positions.

After 6 months - High: Reconcile inter-location stock, open purchasing, cashier activity, exceptions, and manager responsibilities.

After 12 months - High: Coordinate cutover across sites, restore comparable reporting, retrain several roles, and retain historical explanations.

Finance and accounting team

After 30 days - Moderate: Reproduce account mappings, posting rules, access grants, and review procedures.

After 6 months - High if several closes were completed: Transfer outstanding findings, reconciliations, review decisions, and supporting records.

After 12 months - High: Preserve a year of period continuity and evidence relationships. Exported files help, but do not recreate the working review environment automatically.

The likely strongest target is a business large enough to need coordinated operations and accounting, but still struggling with fragmented records. That is a **positioning hypothesis to validate**, not a market finding.

6 Five priorities

Expected benefits below are hypotheses, not quantified forecasts.

Priority 1 Strengthen the daily operating loop

Improvement: Sale to stock to payment evidence to shift close, including interruption recovery.

Retention and customer benefit: Very high potential. Customers repeatedly experience dependable records and faster resolution of discrepancies.

Effort: High.

Prerequisites and principal risk: Representative pilot workflows and runtime measurements. Risk: expanding feature scope before proving the essential loop.

Priority 2 Complete guided cutover

Improvement: Connect existing master-data onboarding to reviewed opening-stock, AR/AP, and accounting workflows.

Retention and customer benefit: High. Customers can move their actual business into Stoquify instead of maintaining parallel spreadsheets indefinitely.

Effort: High.

Prerequisites and principal risk: Existing domain posting controls and reconciliation of opening totals. Risk: importing incorrect financial truth.

Priority 3 Make accountant collaboration a repeatable close service

Improvement: Invitation to evidence request to response to review to retained pack.

Retention and customer benefit: High for the finance-led segment. Saves recurring coordination and preserves institutional knowledge.

Effort: Medium.

Prerequisites and principal risk: Accountants willing to pilot the workflow and clear role permissions. Risk: controls create too much administrative work.

Priority 4 Prove one local integration and country scope deeply

Retention and customer benefit: High for the chosen segment. Reduces manual entry and makes local operating knowledge valuable.

Effort: High; external dependencies.

Prerequisites and principal risk: Real provider specifications/access and qualified review where required. Risk: promising broad automation before proving one path.

Priority 5 Add a complete authorized exit package and explicit service lifecycle

Retention and customer benefit: Medium, indirect retention benefit through trust; high customer benefit. Encourages customers to entrust more important records to the platform.

Effort: Medium to high.

Prerequisites and principal risk: Export inventory, relationship manifest, attachment handling, and access policy. Risk: exposing sensitive data or calling an incomplete archive "complete."

Priorities 1 and 3 primarily strengthen existing workflows. Priority 2 connects existing capabilities and fills cutover gaps. Priorities 4 and 5 require new integration or lifecycle work where current coverage is absent.

7 A practical 90 day sequence

This should be one bounded pilot programme, not a promise to complete every module in 90 days.

Days 1 to 30

Work: Select one customer segment and Cameroon scope. Define activation milestones. Instrument core outcomes. Observe onboarding, checkout recovery, shift close, and accountant review. Inventory export coverage.

Evidence needed to proceed: Baseline completion times, failure causes, recovery outcomes, and precise cutover gaps. Any customer research would be a separately authorized next step.

Days 31 to 60

Work: Address the highest-impact daily workflow problems. Deliver the bounded opening-position journey. Pilot accountant collaboration. Rehearse export and reconstruction for the pilot's records.

Evidence needed to proceed: Opening totals tie out; unresolved operations remain recoverable; users complete core work; archive omissions are explicit.

Days 61 to 90

Work: Pilot one real provider integration if prerequisites are satisfied. Complete the pilot's archive/access policy. Compare adoption cohorts and recurring workflow completion.

Evidence needed to proceed: Current integration evidence, demonstrated migration-package completeness for the agreed scope, and observed repeat use. If external review is missing, keep that capability explicitly gated.

Start measurement in the first period and carry it through all three.

Measure	Definition
Activation	Time from organization creation to validated setup, first successful sale, first reconciled shift, and - where relevant - first reviewed close
Workflow frequency	Organization-days with completed core work, using distinct business-operation IDs rather than page views or retry counts
Module adoption	Eligible organizations completing meaningful transactions in each module; distinguish entitlement, opening a page, and successful use
Team adoption	Active users performing role-relevant work; track cashier, manager, finance, and accountant participation separately
Retention cohorts	Week 1/4/8/12 continued core-workflow use by activation cohort, segment, and adoption depth; separate product inactivity from paid cancellation
Reliability and value	Completion rate, uncertain outcomes, recovery time, unresolved discrepancy age, close duration, and support effort
Reasons for cancellation	Structured reasons plus optional explanation, lost workflow, alternative chosen, migration effort, and whether problems were resolved

Exclude seed/demo organizations and automated jobs. Record outcomes with organization, role, module, timestamp, and correlation identifiers without copying sensitive business payloads into analytics. Treat associations between module depth and retention cautiously: healthier customers may simply adopt more modules.

My commercial judgment

Stoquify's best retention proposition is: **"This is where our team runs the business and can explain its numbers."**

The source supports the potential for customers to stay because Stoquify becomes deeply embedded. It does not yet establish that they stay because the experience is excellent. Nor does it establish that customers are currently being retained by cancellation barriers.

I would invest first in dependable daily operation, successful cutover, and repeated accountant collaboration. More modules or more restrictive access would not address the largest evidence gaps.

Verification performed

• **Source inspection:** Representative routes, actions, services, schemas, exports, access policies, graph nodes, and test definitions reviewed.

• **Workflow check:** npm run agent:workflow:check **passed** after runner and registry inspection; 198 package scripts remain outside the reviewed manifest. This validates workflow controls, not application behavior.

• **Mocked/pure tests:** Definitions inspected, including checkout recovery and current close-proof checks; **not executed**.

- **Real database tests:** A disposable-schema checkout lifecycle test was inspected; **not executed**.
- **Rendered/browser checks: Not performed** for the application.
- **Production usage, paid retention, customer interviews, and live provider operation: Not inspected**.

The assessment was read-only: no files were modified, and no builds, migrations, seeds, graph regeneration, or production-data queries were run during the codebase assessment. This PDF saves that assessment; it does not add new application verification.

Source references

References identify the source locations used in the assessment. Paths below are relative to the repository root. The working-tree context and evidence limits stated in the report apply to all references.
